1 Introdução

No âmbito da unidade curricular Sistemas Operativos foi-nos proposto desenvolver parte do código de vários scripts dados pelo professor, os quais usados em conjuntos permitem simular vários voos e passos deste. Nesse sentido, existem 3 operadores responsáveis pelo processo, a hospedeira, o piloto e os passageiros, e através do uso de semáforos foi possível definir quando e que ações cada um deles devia tomar.

Com efeito, com base nos conteúdos explorados nas aulas teóricas e práticas e alguma pesquisa em fontes externas conseguimos chegar ao resultado esperado. Nesse sentido, no presente relatório descrevemos as metodologias utilizadas para chegar a uma solução, assim como as dificuldades que encontramos e como foram resolvidas.

2 Implementação

2.1 Piloto

Para a nossa simulação da ponte aérea, começamos por implementar o piloto, uma vez que era o mais simples. Nesse sentido, este interveniente pode assumir cinco estados diferentes:

```
/* Pilot state constants */

/** \brief pilot flying to starting airport */

#define FLYING_BACK 0

/** \brief pilot signals ready for boarding */

#define READY_FOR_BOARDING 1

/** \brief pilot wait for boarding to complete */

#define WAITING_FOR_BOARDING 2

/** \brief pilot takes passengers to destination */

#define FLYING 3

/** \brief pilot drops passengers at destination */

#define DROPING_PASSENGERS 4
```

Fig 1 - Estados do piloto

2.1.1 Função flight

Esta função recebe um argumento do tipo booleano, que indica se o piloto está a fazer um voo de *Origin* para *Target* ou vice-versa.

Com efeito, nesta função apenas fazemos alterações dentro da região crítica, nomeadamente, alterar e guardar o estado do piloto para *FLYING* ou *FLYING_BACK*, consoante o argumento *go* seja, respetivamente, verdadeiro ou falso.

```
static void flight (bool go)
    if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (go) {
       sh->fSt.st.pilotStat = FLYING;
       saveState(nFic, &sh->fSt);
   else {
       sh->fSt.st.pilotStat = FLYING BACK;
       saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                               /* exit critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   usleep((unsigned int) floor ((MAXFLIGHT * random ()) / RAND_MAX + 100.0));
```

Fig 2 - Função flight

2.1.2 Função signalReadyForBoarding

Neste excerto, o piloto sinaliza a hospedeira de que o avião está pronto para o embarque. Assim sendo, dentro da região crítica, alteramos o estado do piloto para *READY_FOR_BOARDING* e incrementamos o número do voo, guardando ambos com as funções fornecidas para o efeito.

De seguida, fazemos *up* ao semáforo *readyForBoarding*, o que vai permitir retomar a execução da hospedeira.

```
static void signalReadyForBoarding ()
    if (semDown (semgid, sh->mutex) == -1) {
                                                                                /* enter critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT FAILURE);
   /* insert your code here */
   sh->fSt.st.pilotStat = READY_FOR_BOARDING;
   saveState(nFic, &sh->fSt);
   sh->fSt.nFlight++;
   saveStartBoarding(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                                /* exit critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
    /* insert your code here */
   if (semUp(semgid, sh->readyForBoarding) == -1) {
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
```

Fig 3 - Função SignalReadyForBoarding

2.1.3 Função waitUntilReadyToFlight

Nesta função, o piloto aguarda que o avião esteja pronto para descolar. Por isso, dentro da região crítica, o estado do piloto passa para **WAITING_FOR_BOARDING** e fora desta o semáforo *readyToFlight* fica em down, o que representa a espera do interveniente.

```
static void waitUntilReadyToFlight ()
    if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
      perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.st.pilotStat = WAITING FOR BOARDING;
   saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                              /* exit critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (semDown(semgid, sh->readyToFlight) == -1) {
       perror ("error on the down operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
```

Fig 4 - Função WaitUntilReadyToFlight

2.1.3 Função dropPassengersAtTarget

Nesta parte do *script*, é descrito o processo desde que aterram até que todos os passageiros saem do avião. Portanto, na região crítica inicial, imprimimos no terminal a mensagem de que o avião chegou a *Target* e atualizamos o estado do piloto para *DROPING_PASSENGERS*.

De seguida, num ciclo *for* que é iterado tantas vezes quantos os passageiros no voo atual fazemos *up* do semáforo *passengersWaitInFligth*, o qual os informa de que o voo terminou e podem sair do avião. Após o ciclo, o piloto espera que o último passageiro indique que o avião já está vazio, através do *down* feito ao semáforo *planeEmpty*.

Na segunda região crítica, apenas é chamada a função que imprime a mensagem informativa de que o avião está a regressar a *Origin*.

```
static void dropPassengersAtTarget ()
   if (semDown (semgid, sh->mutex) == -1) {
                                                                                  /* enter critical region */
       perror ("error on the down operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   saveFlightArrived(nFic, &sh->fSt);
   sh->fSt.st.pilotStat = DROPING_PASSENGERS;
   saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                                  /* exit critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   for (int i = 0; i < sh->fSt.nPassengersInFlight[sh->fSt.nFlight-1]; i++) {
       if (semUp(semgid, sh->passengersWaitInFlight) == -1) {
           perror ("error on the down operation for semaphore access (PT)");
           exit (EXIT_FAILURE);
   if (semDown(semgid, sh->planeEmpty) == -1) {
      perror ("error on the down operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   if (semDown (semgid, sh->mutex) == -1) {
                                                                                   /* enter critical region */
       perror ("error on the down operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   saveFlightReturning(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                                 /* exit critical region */
       perror ("error on the up operation for semaphore access (PT)");
       exit (EXIT_FAILURE);
```

Fig 5 - Função dropPassengersAtTarget

2.2 Passageiro

Outro dos intervenientes da nossa simulação da ponte aérea, é o passageiro, cujos quatro estados possíveis são:

```
/* Passenger state constants */
/** \brief passenger is going to the airport */
#define GOING_TO_AIRPORT 0
/** \brief passenger is waiting in queue */
#define IN_QUEUE 1
/** \brief passenger is flying */
#define IN_FLIGHT 2
/** \brief passenger arrives at destination */
#define AT_DESTINATION 3
```

Fig 6 - Estados do Passageiro

2.2.1 Função waitInQueue

Nesta função, é descrito o processo desde que o passageiro chega à fila de espera até que entra no avião.

Assim, começamos por, dentro da primeira região crítica, incrementar o número de elementos na fila e alterar o estado do passageiro atual, cujo id é dado como argumento da função, para **IN QUEUE**.

Seguidamente, o semáforo *passengersInQueue* passa a *up*, permitindo continuar a execução da hospedeira, e damos *down* ao *passengersWaitInQueue*, que coloca o passageiro em espera.

Além disso, na última região crítica, alteramos a variável *passengerChecked* para o id do passageiro atual, já que esta identifica qual o último a ser autorizado a embarcar, e alteramos o estado deste para *IN_FLIGHT*, imprimindo ambas as alterações.

Por fim, permitimos à hospedeira ver a identificação do passageiro dando up ao semáforo *idShown*.

```
static void waitInQueue (unsigned int passengerId)
   if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
      perror ("error on the down operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.nPassInQueue++;
   sh->fSt.st.passengerStat[passengerId] = IN_QUEUE;
   saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                              /* exit critical region */
       perror ("error on the up operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (semUp (semgid, sh->passengersInQueue) == -1) {
       perror ("error on the up operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   if (semDown (semgid, sh->passengersWaitInQueue) == -1) {
      perror ("error on the up operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
      perror ("error on the down operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.passengerChecked = passengerId;
   sh->fSt.st.passengerStat[passengerId] = IN_FLIGHT;
   saveState(nFic, &sh->fSt);
   savePassengerChecked(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                              /* exit critical region */
       perror ("error on the down operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (semUp (semgid, sh->idShown) == -1) {
       perror ("error on the up operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
```

Fig 7 - Função WaitInQueue

2.2.2 Função waitUntilDestination

A função *waitUntilDestination* simula a espera dos passageiros no voo e o desembarque. Portanto, a primeira ação é pôr os passageiros em espera dando *down* ao semáforo *passengersWaitInFlight*.

Posteriormente, entramos na região crítica e decrementamos o número de pessoas no voo e alteramos o estado do passageiro atual para *AT_DESTINATION*. Além disso, quando o número de passageiros passa a zero é dado *up* ao semáforo *planeEmpty*, permitindo ao piloto seguir para o voo de regresso.

```
static void waitUntilDestination (unsigned int passengerId)
    /* insert your code here */
   if (semDown (semgid, sh->passengersWaitInFlight) == -1) {
       perror ("error on the up operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
                                                                                /* enter critical region */
   if (semDown (semgid, sh->mutex) == -1) {
       perror ("error on the down operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.nPassInFlight--;
   sh->fSt.st.passengerStat[passengerId] = AT DESTINATION;
   saveState(nFic, &sh->fSt);
   if (sh->fSt.nPassInFlight == 0) {
        if (semUp(semgid, sh->planeEmpty) == -1) {
           perror ("error on the down operation for semaphore access (PG)");
            exit (EXIT_FAILURE);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                                /* exit critical region */
       perror ("error on the down operation for semaphore access (PG)");
       exit (EXIT_FAILURE);
```

Fig 8 - Função WaitUntilDestination

2.3 Hospedeira

Por fim, temos como entidade principal da ponte aérea a hospedeira, responsável pela maior parte da sincronização da simulação. Pode assumir os seguintes estados:

Fig 9 - Estados hospedeira

2.3.1 Função waitForNextFlight

A função waitUntilNextFlight simula o momento em que a hospedeira espera que o avião retorne do voo anterior. Logo, a primeira coisa a fazer é colocar o estado da hospedeira como WAIT_FOR_NEXT_FLIGHT e depois colocar down o semáforo readyForBoarding.

```
static void waitForNextFlight ()
   if (semDown (semgid, sh->mutex) == -1) {
                                                                              /* enter critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.st.hostessStat = WAIT_FOR_FLIGHT;
   saveState(nFic,&sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                               /* exit critical region */
       perror ("error on the down operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (semDown(semgid, sh->readyForBoarding) == -1) {
       perror ("error on the down operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
```

Fig 10 - Função WaitForNextFlight

2.3.2 Função waitForPassenger

Nesta função, a hospedeira é colocada à espera dos passageiros na fila, por isso o seu estado é alterado para *WAIT_FOR_PASSENGER*, dentro da região crítica.

Também é colocado o semáforo *passengersInQueue* em *down*, deixando a hospedeira em espera.

```
static void waitForPassenger ()
   if (semDown (semgid, sh->mutex) == -1) {
                                                                            /* enter critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.st.hostessStat = WAIT_FOR_PASSENGER;
   saveState(nFic, &sh->fSt);
                                                                           /* exit critical region */
   if (semUp (semgid, sh->mutex) == -1) {
       perror ("error on the down operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   if (semDown(semgid, sh->passengersInQueue) == -1) {
       perror ("error on the down operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
```

Fig 11 - Função WaitForPassenger

2.3.3 Função checkPassport

Nesta função começamos por dar *up* ao semáforo *passengersWaitInQueue*, que permite ao primeiro passageiro da fila avançar.

De seguida, dentro da região crítica alteramos o estado da hospedeira para **CHECK PASSPORT** e fora desta passamos o semáforo *idShown* a *down*.

Na segunda região crítica, é imprimido no terminal o número do passageiro verificado, decrementado o número de passageiros na fila e incrementada a quantidade de pessoas no voo atual e no total de passageiros que já embarcaram em todos os voos.

Além disso, caso o limite máximo de passageiros por voo seja atingido ou tivermos pelo menos o mínimo necessário e não houver nenhum na fila ou ainda se já todos tiverem embarcado o valor de *last* passa a *true*, significando que o avião está pronto para partir. Se, por outro lado, nenhuma destas opções se verificar o valor de *last* é *false* e o estado da hospedeira é alterado para *WAIT_FOR_PASSENGER*.

```
static bool checkPassport()
   bool last:
   /* insert your code here */
   if (semUp(semgid, sh->passengersWaitInQueue) == -1) {
       perror ("error on the down operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   sh->fSt.st.hostessStat = CHECK_PASSPORT;
   saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                               /* exit critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT FAILURE);
   /* insert your code here */
   if (semDown (semgid, sh->idShown) == -1) {
      perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   if (semDown (semgid, sh->mutex) == -1) {
                                                                               /* enter critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   /* insert your code here */
   savePassengerChecked(nFic, &sh->fSt);
   sh->fSt.nPassInQueue--;
   sh->fSt.nPassInFlight++;
   sh->fSt.totalPassBoarded++;
   saveState(nFic, &sh->fSt);
    if (nPassengersInFlight() == MAXFC || (nPassengersInFlight() >= MINFC && nPassengersInQueue() == θ)
       || sh->fSt.totalPassBoarded == N) {
       last = true;
   else {
       last = false;
       sh->fSt.st.hostessStat = WAIT_FOR_PASSENGER;
       saveState(nFic, &sh->fSt);
   if (semUp (semgid, sh->mutex) == -1) {
                                                                               /* exit critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT_FAILURE);
   return last;
```

Fig 12 - Função CheckPassport

2.3.4 Função signalReadyToFlight

A função *signalReadyToFlight* prepara a hospedeira para avisar o piloto de que o avião está pronto para partir. Começamos por guardar o número de passageiros dentro do voo atual (*nPassangersInFlight*) e o estado da hospedeira para *READY_TO_FLIGHT*. Quando o total de passageiros que já embarcaram em todos os voos iguala o número de pessoas que pretendemos deslocar a variável *finished* passa a ter o valor *true*, indicando que este é o último voo a ser feito.

Finalmente, damos *up* ao semáforo *readyToFlight* que indica ao piloto que pode descolar.

```
void signalReadyToFlight()
    if (semDown (semgid, sh->mutex) == -1) {
                                                                            /* enter critical region */
       perror ("error on the up operation for semaphore access (HT)");
       exit (EXIT FAILURE);
    /* insert your code here */
    sh->fSt.nPassengersInFlight[sh->fSt.nFlight-1] = nPassengersInFlight();
    sh->fSt.st.hostessStat = READY TO FLIGHT;
    saveState(nFic, &sh->fSt);
    saveFlightDeparted(nFic, &sh->fSt);
    if (sh->fSt.totalPassBoarded == N)
        sh->fSt.finished = true;
    if (semUp (semgid, sh->mutex) == -1) {
                                                                            /* exit critical region */

3 Resultados

Ao longo da implementação, para verificar se o que estávamos a fazer, compilámos o código à vez com apenas um dos intervenientes feitos por nós, utilizando para os outros dois o código pré-compilado fornecido pelo professor. Para isso utilizámos os comandos *make pt, make pg e make ht*. Com isto foi nos possível identificar mais facilmente a ocorrência de deadlocks e as falhas da nossa implementação.

Após resolvermos todos os problemas que encontrámos executámos o comando *make all* e obtivemos o seguinte resultado.

```

Fig 14 – Resultado da execução do código

Com a implementação descrita obtivemos o seguinte quadro no qual identificamos para cada semáforo utilizado qual a entidade responsável pelos ups e downs, assim como as respetivas funções e quantidades.

Semáforo	Entidade Down	Função Down	#Do wn	Entidade Up	Função Up	#Up
passengersInQueue	hostess	waitForPassenger	21	passengers	waitInQueue	21
passengersWaitInQueue	passengers	waitInQueue	21	hostess	checkPassport	21
passengersWaitInFlight	passengers	waitUntilDestination	21	pilot	dropPassengersAtTarget	21
readyForBoarding	hostess	waitForNextFlight	1 por voo	Pilot	signalReadyForBoarding	1 por voo
readyToFlight	pilot	waitUntilReadyToFlight	1 por voo	hostess	signalReadyToFlight	1 por voo
idShown	hostess	checkPassport	21	passenger	waitInQueue	21

planeEmpty	pilot	dropPassengersAtTarget	1	passenger	waitUntilDestination	1

Fig 15 - Tabela dos semáforos

4 Conclusão

Os scripts desenvolvidos vão de encontro ao proposto, permitindo simular com sucesso vários voos sem que se verifiquem deadlocks durante as ações de cada interveniente.

Com efeito, a realização deste trabalho contribuiu positivamente para o aprofundamento dos nossos conhecimentos no uso de semáforos, através da pesquisa que exigiu, desde com se deve usar corretamente os semáforos e como realizar ações na região crítica. Além disso, temos agora uma melhor noção do que é a shared memory e da sua importância nos scripts.

Durante a execução do trabalho tivemos de lidar com algumas dificuldades, nomeadamente perceber quando ativar e desativar os semáforos, isto é, acertar a sincronização das ações de cada interveniente, mas com recurso aos guiões práticos e alguns sites e de algumas tentativas-erros, conseguimos chegar ao resultado pretendido.

5 Bibliografia

Para a realização deste trabalho consultamos os slides teóricos e os guiões práticos disponibilizados pelo docente, assim como os seguintes sites (consultados entre os dias 21/01/22 e 25/01/22):
